

Figure 8 – Qualitative comparison between the classical Rayleigh-Jeans prediction (dashed blue, $u \propto f^2$, divergent), the experimentally observed Planck distribution (solid black), and the behavior expected from the nonlinear-suppression hypothesis (red dash-dot). When the electric field of the high-frequency modes reaches E_{crit} , the restitutive nonlinearity prevents the indefinite accumulation of energy, producing a natural cutoff at high frequencies qualitatively compatible with the Planck curve. Compare with Figure 13 of Appendix Q.
